

# Nonlinear Systems and Control

Varad Vaidya

January 12, 2024

Lecture notes from the 2024 graduate course Nonlinear Systems and Control, given by professor Pavankumar Tallapragada at IISc Bangalore in the academic year 2023-23. Credit for the material in these notes is due to professor Pavankumar. The credit for the typesetting is my own, along with any contributions from the PRs, of the notes hosted on GitHub.

*Disclaimer:* This document will inevitably contain some mistakes— both simple typos and legitimate errors. Keep in mind that these are the notes of a graduate student in the process of learning the material, so take what you read with a grain of salt. If you find mistakes and feel like telling me, I will be grateful and happy to hear from you, even for the most trivial of errors. You can reach me by email at [vaidyavarad2001@gmail.com](mailto:vaidyavarad2001@gmail.com).

# 1 Lecture 3 — Linearization

## 1.1 Linearization

Consider a non linear system  $\dot{x} = f(x)$  with an equilibrium point  $x^* = 0$ . Then using first order Taylor series expansion, we have:

$$\dot{x} = f(x) = f(0) + \left. \frac{\partial f}{\partial x} \right|_{x=0} x + \mathcal{O}(x^2)$$

Thus, the linearised system can be written as:

$$\dot{x} = Ax \quad \text{where} \quad A = \left. \frac{\partial f}{\partial x} \right|_{x=0}$$

The matrix  $A$  is called the *Jacobian* of the system  $\dot{x} = f(x)$  evaluated at the equilibrium point  $x^* = 0$ . The system can also be calculated for an equilibrium point not at origin, by shifting the origin to the equilibrium point.

### 1.1.1 Perturbations of the eigenvalues

The study of the behaviour of linear systems about the equilibrium point  $x = 0$  is important because in many cases the behaviour of a nonlinear systems, near an equilibrium point can be deduced by linearising the system about the equilibrium point.

The validity and the accuracy of the linearization of the nonlinear system, and the resultant qualitative behaviour depends on the placement of the eigenvalues of the linearised system. This can be understood by considering the linear perturbations. Let the linearized system be given by  $\dot{x} = Ax, x \in \mathbb{R}$ , with distinct eigenvalues, and let  $\Delta A \in \mathbb{R}^{2 \times 2}$  be a small perturbation matrix, whose elements have arbitrary small magnitudes. We know, that the eigenvalues of the matrix  $A + \Delta A$  depend continuously on the parameters of the matrix.

Thus, when the matrix  $A$  is perturbed by  $\Delta A$ , any eigenvalues of  $A$  that lies in the left or the right half plane, will remain in its respective half plane. But, the eigenvalues on the imaginary axis, when perturbed might go into either the left or the right half plane.

Consequently, we can say that if the equilibrium point  $x = 0$  of  $\dot{x} = Ax$  is a node, focus, or saddle, then the equilibrium point  $x = 0$  of  $\dot{x} = (A + \Delta A)x$  will be of the same type, provided that the perturbations are small enough. This situation is quite different in the case of center. Since the qualitative behaviour of the stable focus and unstable focus are different from that of a center, the center equilibrium point will not persist under perturbations.

The node, focus, and saddle equilibrium point are said to be *structurally stable* because they maintain their qualitative behaviour under infinitesimally small perturbations.

#### Definition 1.1: Hyperbolic Equilibrium Point

An equilibrium point of the system  $\dot{x} = f(x)$  with  $f(x^*) = 0$  is said to be hyperbolic if:

$$\Re \left( A = \left. \frac{\partial f}{\partial x} \right|_{x=x^*} \right) \neq 0$$

i.e. the jacobian of the system evaluated at the equilibrium point has no eigenvalues with zero real part.

**Example.** Consider the system  $\dot{x} = x^3, x \in \mathbb{R}$ . The system has its only equilibrium point at  $x^* = 0$ . The phase portrait of the system is given by:

linearising the system we have  $\dot{x} = 3x^2 \Rightarrow \dot{x} = 0$ .

Thus we can say that for any arbitrary point close to the equilibrium point, the behaviour described by the linear system is different from the non linear system

**Example.** Consider the system given by:

$$\begin{aligned}\dot{x}_1 &= -x_2 - \mu x_1(x_1^2 + x_2^2) \\ \dot{x}_2 &= x_1 - \mu x_2(x_1^2 + x_2^2)\end{aligned}$$

The system has an equilibrium point at  $x^* = 0$ . Linearising the system around the origin we have:

$$A = \left. \frac{\partial f}{\partial x} \right|_{x=0} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \Rightarrow \lambda = \pm i$$

Note that the linearised system corresponds to a simple harmonic oscillator

Shifting, into polar coordinates to analyse the system, we have:

$$r := \sqrt{x_1^2 + x_2^2} \quad \theta := \arctan\left(\frac{x_2}{x_1}\right)$$

After some simplification, we have:

$$\dot{r} = -\mu r^3 \quad \dot{\theta} = 1$$

Depending upon the value of  $\mu$ , we have the following:

$$\mu > 0 \Rightarrow \text{Stable Focus}$$

$$\mu = 0 \Rightarrow \text{Center}$$

$$\mu < 0 \Rightarrow \text{unstable Focus}$$

Thus, the qualitative behaviour is same for the linearised system and the nonlinear system, only at  $\mu = 0$ , which can also be trivially observed from the state equations.

Thus, we have a sufficient condition for the qualitative behaviour of the nonlinear system to be same as the linearised system, which is that the equilibrium point of the nonlinear system should be hyperbolic.

**Theorem 1.1 (Hartman-Grobman Theorem).** Let  $\dot{x} = f(x)$ ,  $x \in \mathbb{R}^n$  be a nonlinear system with an hyperbolic equilibrium point  $x_e$ . Let  $\phi_t^f$  be the flow map for  $\dot{x} = f(x)$  i.e.  $\dot{x} = f(x)$ ,  $x(0) = x_0$  has the solution  $x(t) = \phi_t^f(x_0)$ . Then for a  $\delta > 0$  and a ball  $B_\delta(x \in \mathbb{R}^n | \|x - x^*\| < \delta)$  there exists as map  $F : B_\delta \subset \mathbb{R}^n \rightarrow \mathbb{R}^n$ ,  $\exists T > 0$  such that,

$$F(x_e) = 0, \text{ F is one to one on } B_\delta \text{ onto } F(B_\delta)$$

and both  $F$  and  $F^{-1}$  exists and are continuous, such that  $F(\phi_t^f) = e^{At}F(x)\forall |t| < T$ . Where  $A = \left. \frac{\partial f}{\partial x} \right|_{x=x^*}$  and  $x \in B_\delta$

The map  $F$  in [Theorem 1.1](#) maps from the nonlinear world to the linear world.
